Transmission Line; The waveguide is a hollow metallic structure through which electric and magnetic fields are transmitted. The transmission line is a conductor which is used to carry electrical signal over a long range. It has simple to manufactured. It has complex to manufactured. In waveguide the power handling is high as compared to transmission line.

A waveguide is a special form of transmission line consisting of a hollow, metal tube. The tube wall provides distributed inductance, while the empty space between the tube walls provide distributed capacitance. Wave guides conduct microwave energy at lower loss than coaxial cables.

Waveguides Waveguides Waveguides, like transmission lines, are structures used to guide electromagnetic waves from point to point. However, the fundamental characteristics of waveguide and transmission line waves (modes) are quite different. The differences in these modes result from the basic differences in geometry for a transmission line and a waveguide. Waveguides can be generally

Definition: Waveguides are a special category of transmission line that is used to guide (direct) the waves (radiation) along the length of the tube. These are typically hollow metallic tube which acts as the medium to transfer or transmit the power. In waveguides, the energy is propagated through a tube.

For a uniform transmission line, the voltage (and current) propagates along the line as a wave. The voltage along the line must be of the form  $V(x,t)=f(x-vt)$  or  $V(x,t)=g(x+vt)$ , or a sum of both.

In radio-frequency engineering, a transmission line is a specialized cable or other structure designed to conduct alternating current of radio frequency, that is, currents with a frequency high enough that their wave nature must be taken into account. Transmission lines are used for purposes such as connecting radio transmitters and receivers with their antennas, distributing cable television signals, trunklines routing calls between telephone switching centres, computer network connections and

~~Transmission Lines Vs Waveguides~~. The main difference between a transmission line and a wave guide is □ A two conductor structure that can support a TEM wave is a transmission line. A one conductor structure that can support a TE wave or a TM wave but not a TEM wave is called as a waveguide. The following table brings out the differences between transmission lines and waveguides.

Waveguides are a special form of transmission line used for microwave applications. They are metallic tubes made often of high quality material (copper, brass - partially silvered or gold plated even). In the latest technology these waveguides are produced as electrically copper plated very light carbon fiber composites.

Waveguides will only carry or propagate signals above a certain frequency, known as the cut-off frequency. Below the waveguide cutoff frequency, it is not able to carry the signals. In order to carry signals a waveguide needs to be able to propagate the signals and this is dependent upon the wavelength of the signal.
